

MARKETING PERFORMANCE & CAPACITY ANALYSIS

Management Insight & Recommendation

Final validated analysis based on BigQuery + Looker Studio

1. Executive Summary

This analysis evaluates marketing acquisition, customer quality and helper capacity together. The key conclusion is that marketing efficiency should not be assessed using ROAS or normal CPA alone; recurring-customer quality and operational capacity must also be considered.

Metric	Result
Total Ad Spend	\$13,300
CRM Leads	462
Unique Potential Customers	454
New Paying Customers	138
New Recurring Customers	48
CPA	\$96.38
Recurring CPA	\$277.08
Revenue Excluding GST	\$26,628
ROAS	2.00x
Available Helper Hours	4,043
Booked Helper Hours	3,136
Vacant Helper Hours	907
Helper Utilisation	77.57%

2. Marketing Performance — Q1

Total ad spend is \$13,300, generating 462 CRM leads, 454 unique potential customers, 138 new paying customers and 48 new recurring customers. Revenue excluding GST is \$26,628, producing a 2.00x ROAS. CPA is \$96.38 and recurring CPA is \$277.08.

The 454 unique potential customers is lower than 462 CRM leads because the same Customer_ID can appear across multiple leads. Customer-level potential customers were therefore deduplicated using a first-touch attribution rule.

3. Strongest Platform / Campaign / Ad — Q2

Campaign	Evidence	Interpretation
G_Search_Weekly	36 paying; 26 recurring; ~72.2% recurring rate	Strongest customer-quality contributor; candidate for controlled scaling.
M_Deep_BeforeAfter	ROAS 5.29x; \$10,060 revenue; 20 paying	Strongest revenue efficiency; scale selectively and validate recurring quality.
Ad / Creative level	Evaluate paying conversion + recurring quality + ROAS together	The strongest ad should be selected using the same multi-metric logic, not ROAS alone.

The answer changes depending on the objective: M_Deep_BeforeAfter is strongest for revenue efficiency, while G_Search_Weekly is stronger for recurring-customer quality.

4. Campaigns to Reduce / Stop / Investigate — Q3

Campaign	Signal	Action	Reason
M_Price_Offer	ROAS 0.59x; 11 paying; 2 recurring; recurring CPA \$800	Reduce/pause current setup and retest	Weak revenue efficiency and poor recurring quality.
G_Search_Adhoc	ROAS 0.78x	Investigate	Review keywords, search intent, targeting and conversion before scaling.

5. Data Quality & Attribution — Q4

- Unique potential customers were initially overstated because the same Customer_ID could occur across multiple leads/campaigns. A first-touch rule was applied so each customer is counted once for this KPI.
- Paid-customer metrics were linked through Lead_ID while marketing performance was aggregated at Platform → Campaign → Ad Set → Ad Creative.
- The helper-capacity source contained malformed hour values: 5, 15, 25 and 35 represented 0.5, 1.5, 2.5 and 3.5 hours. These were normalized before aggregation.
- The cleaned capacity data was validated using Available Hours = Booked Hours + Vacant Hours: 4,043 = 3,136 + 907, giving 77.57% utilisation.

6. Helper Capacity — Q5

Capacity KPI	Result
Total available capacity	4,043 hours
Booked hours	3,136 hours
Vacant hours	907 hours
Utilisation	77.57%

7. Shift Utilisation & Marketing Implication — Q6

Shift	Utilisation	Interpretation	Marketing implication
Morning	87.67%	Highest utilisation	Avoid concentrating incremental demand here; monitor bottleneck risk.
Afternoon	80.00%	Moderately high	Can absorb some incremental demand.
Evening	60.30%	Largest spare capacity	Prioritize demand generation/offers that can shift bookings into Evening.

Marketing and operations should coordinate campaign timing and offers so incremental demand is directed toward lower-utilisation periods, particularly Evening.

8. Additional Customer Capacity — Q7

Using the observed average first-30-day booked hours per new paying customer of approximately 8.67 hours:

$$907 \text{ vacant hours} \div 8.67 \text{ hours/customer} \approx 104.6 \text{ customers}$$

Therefore, the remaining helper capacity could theoretically support approximately 104 additional new customers, assuming the observed average first-30-day hours remains stable.

9. Theoretical Incremental Budget — Q8

Using the current actual new-customer CPA of \$96.38:

$$\approx 104.6 \text{ customers} \times \$96.38 \text{ CPA} \approx \$10.1\text{K}$$

The ~\$10.1K figure is a theoretical budget ceiling, not an immediate spending recommendation. CPA can rise as spend scales, incremental leads may have weaker conversion or recurring quality, and shift-level

capacity can become a bottleneck. Management should start with a controlled 10–20% budget increase and scale only if CPA, recurring rate, ROAS and helper utilisation remain acceptable.

10. Top 5 Recommendations to Management — Q9

1. Scale G_Search_Weekly gradually

It contributes the highest number of recurring customers. Increase budget in controlled steps while monitoring recurring rate and CPA.

2. Selectively scale M_Deep_BeforeAfter

Its 5.29x ROAS is the strongest revenue-efficiency signal. Validate recurring quality before aggressive scaling.

3. Reduce and retest M_Price_Offer

ROAS of 0.59x and recurring CPA of \$800 indicate poor economics and weak customer quality. Review offer, audience and creative.

4. Shift incremental demand toward spare capacity

Evening has the lowest utilisation at 60.30%. Avoid creating a morning-heavy operational bottleneck.

5. Use controlled test-and-learn scaling

Treat ~\$10.1K as a theoretical ceiling. Start with a 10–20% incremental spend test and monitor CPA, recurring rate, ROAS and helper utilisation.

11. Reporting Automation — Q10

A real-business reporting pipeline should automate data ingestion, transformation, validation and BI delivery:

Advertising APIs can provide spend, campaign, ad set and creative metrics. CRM/payment events can be captured through database connectors or webhooks. BigQuery acts as the central warehouse and transformation layer, while scheduled queries perform deduplication, attribution and data-quality checks.

Looker Studio consumes curated views. Alerts can be added when CPA rises, recurring rate falls or helper utilisation approaches a defined threshold.

12. Final Conclusion

The key management decision is not simply to spend more. The business has 907 vacant helper hours and theoretical capacity for approximately 104 additional customers, but growth should be directed toward high-quality acquisition and lower-utilisation periods. G_Search_Weekly is the strongest recurring-quality scaling candidate, M_Deep_BeforeAfter is the strongest revenue-efficiency candidate, and M_Price_Offer requires optimization. A controlled scaling approach reduces the risk of buying low-quality customers or creating an operational bottleneck.
